Atlanta, March 28, 2019.
Thanks to Mars Stone, Inderdeep Singh and Honey Dave for additional testing

## Disclosures

All authors receive grant support and/or have consulting agreements with Sedia Biosciences Corporation.

The company had no role in data generation, interpretation or analysis.

## THESE DATA AND RESULTS ARE PRELIMINARY AND SUBJECT TO CHANGE.

## Background

- CEPHIA conducted an independent evaluation of the Sedia ${ }^{\text {TM }}$ Asanté HIV-1 Rapid Recency Assay
- PoC lateral flow assay with Control (CTRL), Verification (VER) and Long-term/Recent (LT/R) lines
- Evaluation focused on reproducibility and the HIV incidence surveillance use case
- We tested the
- CEPHIA Qualification Panel
- 250 specimens
- including 10 replicates each of 5 blinded reproducibility control specimens
- each specimen tested 6 times
- CEPHIA Evaluation Panel
- 2,500 specimens spanning range of times since infection for robust estimation of mean duration of recent infection (MDRI) and false-recent rate (FRR)
- 25 replicates each of three blinded reproducibility controls
- tested according to the SOP/package insert

## Procedures

- Strips can be interpreted visually or using an electronic reader
- Visual interpretation:
- line intensities scored on an ordinal scale (0-4)
- primarily absence/presence of CTRL, VER and LT/R lines (i.e. 0 or $\geq 1$ )
- negative verification line triggers serological confirmation and re-testing
- unverified specimens are not given a recency interpretation
- Reader interpretation:
- line intensities recorded under standard lighting conditions
- negative VER triggers serological confirmation, borderline VER results trigger confirmatory testing (final result - median of three)
- borderline LT/R results trigger confirmatory testing (median of three)

## Performance for incidence surveillance

## Methods

- We use CEPHIA Evaluation Panel data to estimate mean duration of recent infection (MDRI) and false-recent rate/proportion false-recent (FRR)
- MDRI: Average time post-infection a subject spends exhibiting the 'recent' marker
- FRR: Proportion of long-infected subjects who nevertheless exhibit the 'recent' marker
- For the primary analysis we ignore verification status of specimens
- this is favorable to the assay, since we are obtaining recency interpretations where current SOP does not allow an interpretation
- we recommend that valid results from confirmed seropositive specimens that fail to verified be interpreted as recent
- We evaluate performance (precision of incidence estimates) in three epidemiological/surveillance scenarios

## Results: 'standard’ recency discrimination thresholds

| Algorithm | MDRI (Model A) PE ( $95 \%$ CI) | MDRI (Model B) $\text { PE ( } 95 \% \text { CI) }$ | $\underset{P E}{M D R I(W B)}$ | MDRI (4thgen RT) PE | MDRI (4thgen lab) PE | FRR (naïve) PE (95\% CI) | FRR (suppressed) PE (95\% CI) |

[^0]
## Results: MDRI vs. LT/R threshold (reader)

## Results: FRR vs. LT/R threshold (reader)

## FRR (treatment naïve, non-EC) vs. MDRI

## Context-specific FRR vs. LT/R threshold (reader)

## Precision of incidence estimates vs. LT/R threshold (reader)

## Conclusions

- Sensitivity of the verification line is good on strongly antibody-positive, untreated specimens specimens, but
- sensitivity is lower in when very recently-infected and virally suppressed specimens are included
- exclusion of confirmed positive but verification line non-reactive specimens from the recency interpretation would reduce precision of incidence estimates
- The Sedia Asanté HIV-1 Rapid Recency assay's performance is acceptable for use in population-level incidence surveillance, but must be combined with a supplemental viral load threshold to achieve acceptable FRR
- MDRI is substantially lower when visually interpreting the LT/R line
- Alternative (higher) LT/R thresholds should be considered when using the test strip reader to increase MDRI

[^0]:    * Correction (April 10, 2019): The original slides presented contained incorrect FRR estimates for these algorithms.
